Block 1: create your first repository

Step 1. Create a new repository in GitHub Desktop

- Open GitHub Desktop and go to File --> New repository...

- The following windows open:

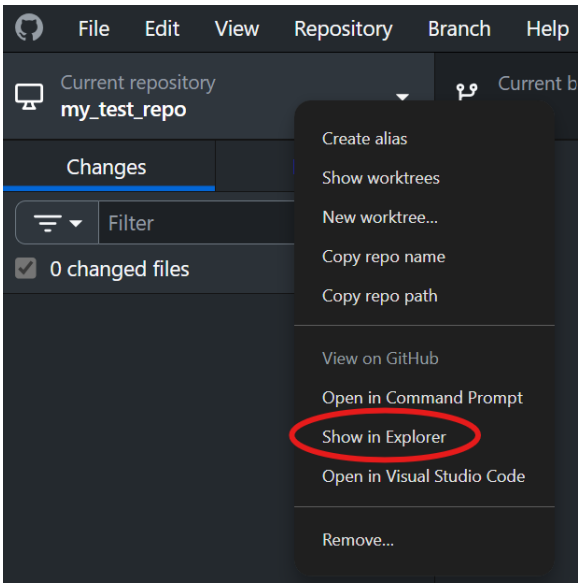

- As a name, choose: `my_test_repo`
- Local path: choose where to store it on your computer (e.g., your Documents folder). GitHub Desktop creates the folder `my_test_repo` there
- Do **not** tick “Initialize this repository with a README” (you will add your README in Step 2)

- Click “Create repository”

Your folder is now a **Git repository**: Git can track every change made inside it. For the moment, it only exists on your computer.

Step 2. Add the example files

- Open the folder in your file explorer/Finder: Right click on "Current repository", and click on "Show in Explorer"/"Show in Finder"

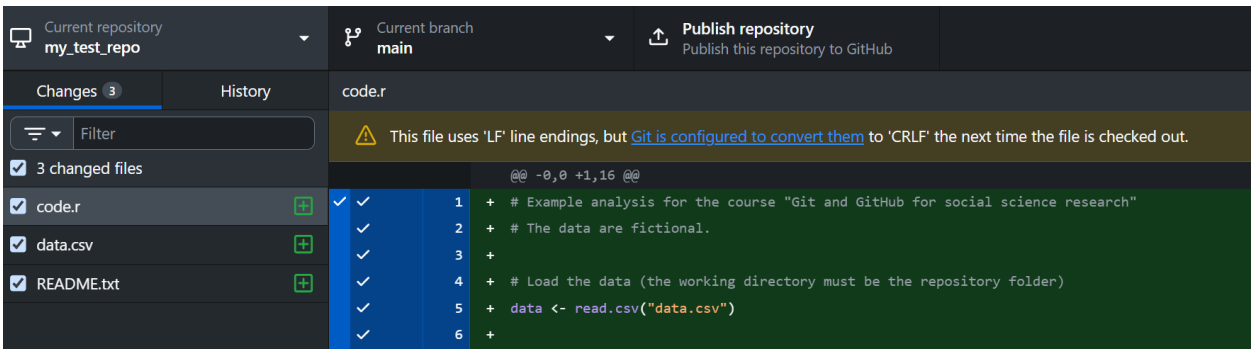

- Add the 3 files we sent you, README.txt, code.r, data.csv, to the "my_repo_folder" folder

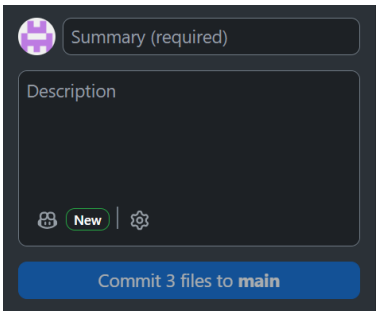

Step 3. Add, commit, and publish

- Go back to GitHub Desktop. The three files appear in the “Changes” tab with a green "+" symbol, meaning that these files were added. This is exactly the role of Git/GitHub: it tracks what changes in your repository.

  Note: On Windows, GitHub Desktop may warn that the files use "LF" line endings. You can ignore it: it only concerns how line breaks are stored.

- Write a summary at the bottom left (e.g., “Add example files”) and click “Commit to main”

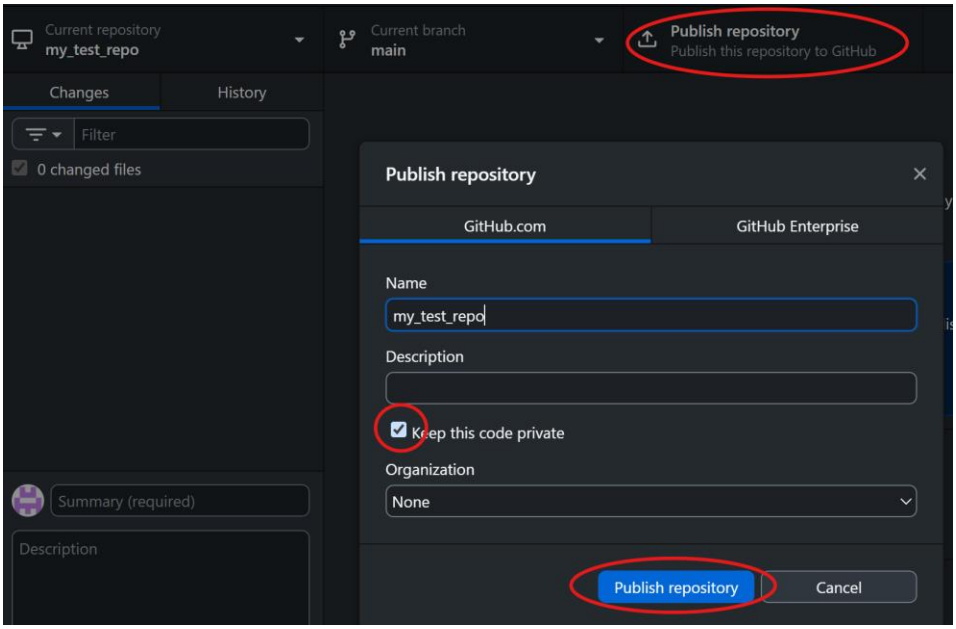

Some vocabulary

Add = select the files and corresponding changes to save

Commit = save a snapshot of the current version of your code, with a small message

- Click “Publish repository” (top bar). Keep “Keep this code private” ticked and click “Publish repository”

"Publish" here means your repository now exists also on GitHub, not just on your computer. Because you decided to keep your code private, only you can see this code online.

Your notes:
